 INDUSTRY BRIEFS

Price Increases

- **Allied Air Enterprises** (Columbia, S.C.) increased prices up to 5 percent on commercial products and accessories, effective Jan. 1, 2009.
- **Lennox Industries Inc.** (Dallas) increased prices up to 5 percent on commercial products and accessories, effective Jan. 1, 2009.

Contractors

- **Walker-J-Walker**, a subsidiary of **EMCOR Services** (Memphis, Tenn.), relocated its headquarters to 54,000 square feet of new space at 6045 East Shelby Drive in Memphis, Tenn.
- **Ductz Indoor Air Professionals** (Ann Arbor, Mich.) appeared on the television show "Designing Spaces," educating viewers about IAQ.

Manufacturers

- **Home Comfort Zones Inc.** (Portland, Ore.) appointed **Western Heating & Air Conditioning** (Boise, Idaho) as its authorized dealer for the Boise, Idaho, market.

Distribution

- **Industrial Controls Distributors LLC** (Wanamassa, N.J.) hired **Peter Tomczyk** as branch sales manager for its Milwaukee office.

Organizations

- **Nexstar Network** (Little Canada, Minn.) selected **Cube Six Inc.** (Matthews, N.C.) to provide its members with **ServMan**, an enterprise management system software package.
- **The Hydraulic Institute (HI)** made the educational presentations from its annual meeting available at its Website, www.pumps.org.

— compiled by Angela D. Harris

NCI Announces Acquisition of ISL

SHEFFIELD LAKE, Ohio — At the International Service Leadership (ISL) Owners Conference, it was announced that the National Comfort Institute (NCI) has acquired ISL.

NCI has long been known as a leader in providing professional training on topics such as air diagnostics, air balancing, carbon monoxide detection, combustion efficiency, and overall HVAC system performance. Over its 15 years in business, NCI has trained over 15,000 HVAC profes-

sionals in various technical disciplines.

ISL has evolved from the 1990 membership organization named Contractor's Success Group. Through the years ISL has taken many forms but most recently was owned and operated by three leading contractors. ISL's focus has always been to help its membership with sales, service and general business practices.

Late in 2007 the principals at NCI and ISL began working on a joint program for ISL members titled SCCRE (Seasonal Calculated

Operational Running Efficiency). During this project, the two companies realized how well they complimented each other and the idea of joining talents hatched.

Milt Baum, president of ISL and owner of Keil Heating in Patterson, N.J., remarked "the background and resources of NCI will be a major value to the ISL membership. Together we will be able to help our members grow in ways that we never could as separate companies. I see NCI and ISL as experienced

Preventing Mold Growth in Hospitals

CONSULTANT ENCOURAGES SCRUTINY OF HVAC DESIGN IN HEALTH CARE FACILITIES

By Mark Skaer
 Of The NEWS Staff

Mark Nunnally will be the first to tell you that there are no guarantees to yield a zero mold growth in a health care facility. To prove his point, all the president of Nunnally & Associates, based in Birmingham, Ala., has to do is turn to American Society of Heating, Refrigerating and Air-Conditioning Engineers' (ASHRAE's) *HVAC Design Manual for Hospitals and Clinics*, which states, "health care facilities are environments of controlled hazards."

In other words, the hazards — molds, bacteria, viruses, etc. — are there. The challenges, maintains Nunnally, is controlling these hazards to a level, as he put it, "deemed safe for the facility's occupants, patients, and caregivers."

"Oftentimes, the root causes of mold-related problems in health care facilities can be traced back to shortcomings with the initial facility design," said Nunnally, who specializes in humidity control consulting. "These shortcomings often

CHIL-PAK[®]

PACKAGED CENTRAL PLANT BY AIR MATRIX

The Chil-Pak[®] Central Plant Solution™

- Integrated packaged central plants from 150-1500 tons
- 2" double wall construction
- Single point electric and controls
- Design assistance and field support
- ETL labeled in ISO 9000:2001 certified facility
- Ultra-efficient chiller and boiler plants also available

Benefits

- 10-15% first cost savings vs. site built central plants
- Reduce lead time with pre-engineered solutions
- Minimize field labor risk and cost
- Consolidated system responsibility
- 1/3 the size of a field constructed plant

PREVENT MOLD

continued from page 1

pertain to the building structure itself — the building envelope, the building materials used, etc. Other design shortcomings, however, are often related to the HVAC system and its ability, or lack thereof, to control the patient care environment to conditions that are not conducive to mold growth."

Even if all of the bases were covered properly during the design phase, and the facility was built in accordance with the design standards and documents, mold can often still be found in a building because of the way in which the building and its HVAC system are being operated and maintained, he said.

DESIGN ISSUES

In Nunnally's estimation, many design issues can lead to a lack of moisture control within a

hospital that can potentially lead to mold problems. These issues could be building envelope- and construction-related, such as poor or improper insulation leading to wall surface condensation. The problems might be improper roof drainage, leaky window and door systems, improper installation of vapor retarders, or any number of envelope-related issues, he said. It might very well be related to having too much water and/or humidity entering the building during the construction phase.

Zeroing in strictly on the HVAC system's design and operation, Nunnally believes there are a number of issues that must be resolved before the proper HVAC system can be designed, whether it be intended for the surgical suite, the patient rooms, or the administration offices.

"Initially, the proper ambient design conditions must be selected," he said. "Too often, only the peak cooling design conditions are considered for sizing the capacity

mold dangers

According to the Environmental Protection Agency (EPA), many mold types are very opportunistic and will often infect those people with weakened immune systems (i.e., immuno-compromised individuals). *Aspergillus fumigatus*, for example, has been known to infect the lungs of immuno-compromised individuals. These individuals inhale the mold spores, which start growing in their lungs.

Trichoderma has also been known to infect immuno-compromised children. Other health effects can range from simple headaches, sinus, or breathing problems to more severe problems like skin rashes, bleeding of the lungs, cancer, and even death.

There is evidence that a direct association exists between exposure to mold and adverse health effects. Mayo Clinic investigators have recently found that inhaled fungus and mold trapped in the nasal mucus are a major cause of sinusitis. There is also other suggestive evidence that there is an association between exposure to mold and other adverse health effects. ■

requirements of the system. These ambient conditions are listed in the *ASHRAE Handbook — Fundamentals* as the dry bulb temperatures with mean coincident wet bulb temperatures, representing conditions on hot, mostly sunny days. These conditions are used in sizing cooling equipment, such as chillers or air conditioning equipment for cooling control.

"In some climates, this might be satisfactory. However, in geographic areas known for higher humidity levels, considering only this cooling condition might not be sufficient."

According to Nunnally, extreme dew point temperature conditions may occur on days with moderate dry bulb temperatures, resulting in high relative humidities and peak absolute moisture loads from the weather. He said these values from tables found in the *Fundamentals* handbook are useful for humidity control applications, such as desiccant cooling and dehumidification, cooling-based dehumidification, and fresh air ventilation systems.

"These values can also be used as a checkpoint when analyzing the behavior of cooling systems at part-load conditions, particularly when such systems are used for humidity control as a byproduct of temperature control," he said, noting that the psychrometric chart for Memphis, Tenn. (see Figure 1), highlights what a significant impact the selected ambient extremes can make. As seen in Figure 1, if the space were to be maintained at a condition of 75°F dry bulb (db) and 50 percent relative humidity (rh), the ventilation air being introduced during the extreme dew point condition would require much more dehumidification capacity than the ventilation air at the extreme cooling condition, he explained. This means almost 52 percent more dehumidification capacity is required just to deliver the ventilation air at a space "neutral" humidity level.

"Not considering the more difficult peak dew point conditions of the ambient air is one of the major reasons that HVAC systems in the hospitals cannot adequately control the humidity during much of the year," said Nunnally.

DEALING WITH COOLER CONDITIONS

Nunnally maintains that another reason humidity and condensate problems are being seen in hospitals, particularly within surgical suites, is that the rooms are being kept at cooler conditions than for that which the engineer designed the HVAC system. Most of the time only the general requirements from the American

Institute of Architects (AIA) guidelines are considered for the surgical environment's temperature and humidity range, for example 68°db and 50 percent rh.

"However, nothing in these guidelines shall be construed as precluding the use of temperatures lower than those noted when the patients' comfort and medical conditions make lower temperatures desirable. Some surgeons may require room temperatures that are outside of the

indicated range," he said.

"All operating room design conditions shall be developed in consultation with surgeons, anesthesiologists, and nursing staff. The designer must ask the end users of the facilities what the anticipated space conditions will be." If the HVAC system had only been designed to maintain the space at the higher room temperatures, Nunnally said then once the room's temperature is actually lowered (e.g., 60° to 62°db),

then the HVAC system's capacity would very likely not be able to reach the necessary lower absolute moisture levels for the space.

"If this occurs, the moisture in the air will begin to condense on the cooler surfaces of the ceiling supply air diffusers, the suspended fixtures, and even on the surgical equipment and tables," he said.

"Condensate raining from the ceiling, after being in contact with the dirt, dust, and mold spores is certain to cause con-

cerns regarding the sterility of the surgical environment."

He noted that this same phenomenon can happen in other parts of the hospital, including kitchen and dining, labs, and even patient rooms. However, the surgical environment is generally the more common area of concern, he said.

"This is the primary reason the desiccant-based dehumidification systems are becoming much more of a standard in the surgical suites," he added.

For your HVAC System, Home, and Family.

Clean air by Field Controls.

It's not just UV, mold control, filtration, or air changes. Field Controls has a complete package of clean air products that attack IAQ problems at the source. With in-duct and portable models, Field Controls has a solution for virtually any home or small business environment.

Field Controls products allow you to customize a solution that fits your needs. Be sure to ask your wholesaler or visit our website for more information. When it comes to clean air, you need the complete package from Field Controls.

SOME EXAMPLES

Nunnally's bottom line is this: Proper selection, sizing, and application of the HVAC systems are essential to ensuring the humidity is controlled to a level to where there is minimal chance the moisture in the air will condense and provide the mold spores with the moisture it needs to flourish. Mechanical HVAC systems — including chilled-water systems and/or direct expansion systems — must be selected with the cooling coils capable of supplying air at dew points low enough to actually compensate for the moisture gain within the spaces (i.e., latent gain), he noted.

Nunnally used the following as an example. If the operating space is to be maintained with a condition of 60° db and 50 percent rh, then a chilled-water coil only capable of delivering air off the cooling coils at 50° to 52° (saturated) will not satisfy the need. He said the

pay attention

In addition to design issues, consultant Mark Nunnally said maintaining a clean environment, including a clean HVAC system, will pay great dividends toward minimizing the potential for mold growth in hospitals.

“Food for mold spores is generally in abundance within the facility, but there is no reason to spoon-feed the mold spores,” said the president of Nunnally & Associates. “Keep the air handlers’ filters clean, and keep the dust and dirt out of the space as much as possible.”

If remodeling projects are underway within the hospital, even if it involves simply running new cables above a ceiling system, Nunnally encouraged the practice of sealing off the construction areas to make certain the airborne debris is unable to get into the areas that should be clean.

“As a preventive measure, consider engaging the services of an industrial hygienist to assist,” he suggested.

In an effort to conserve energy, Nunnally said oftentimes the chiller is allowed to operate with a slightly elevated leaving water temperature (e.g., elevating from 44° to 46°, possibly). While this will indeed save on the energy bill, and it might be sufficient for keeping the space temperature under control, “it could fail miserably at controlling the moisture within the space, especially within the operating rooms,” he said.

He added, “If the humidity within the space should exceed the desired maximum acceptable level — for instance, 55 percent to 60 percent rh — then there should be a humidity sensor and transmitter within the space that could override the temperature controls and then lower the chilled-water temperature in order to keep the humidity under control.”

In the overall picture, he said building pressurization is another critical factor to monitor in a hospital, as it can greatly affect the controllability of the environment. If the building pressure is allowed to become negative due to supply filters being loaded, supply fans running too slow, or return fans running too fast, humid and dirty air can be drawn into the building through cracks and openings, he explained.

“This air is completely unconditioned and can provide several of the necessary ingredients to promote mold growth,” he said, meaning moisture, more spores, and nutrients. “Dynamic pressure differential monitoring must take place in order to ensure the building is under the necessary positive pressure.”

He advised also to regularly have a testing, adjusting, and balancing (TAB) evaluation performed on the facility's HVAC systems. At the same time, examine those drain pans.

“It is far too common to see water standing in drain pans due to either clogged condensate lines, pans that are not sloped, or drain line connections placed too high above the drain pan's floor,” he said. “If there is water standing in the pans, then this water can become a breeding ground for hazardous bacteria and molds. Much of this standing water will also be evaporated back into the supply airstream, saturating the supply duct, making it a prime breeding ground for undesirable hazards.”

Even though some of these issues might be obvious, Nunnally said these are some of the more common issues found in the design and operation of the health care facilities.

“Excessive mold growth has been found in too many instances within the facilities that should be the healthiest of them all,” he said. “Greater attention must be paid, in the design and in the operational phases, to the HVAC system's capability to actively control the humidity within health care facilities.” ■

supply air would have to be delivered at an absolute humidity level of less than 41.3° dew point.

“This would require either a low-temperature chiller or a desiccant-based dehumidification/cooling system,” said the consultant.

For a facility only trying to maintain the space at 75° db and 50 percent rh (i.e., 55° dew point), Nunnally said the coils must still be capable of delivering air with a dew point less than 55° in order to absorb the space latent gain.

“If the moisture is not controlled sufficiently by the HVAC system, this could spell disaster with regard to trying to keep significant mold growth out of the facility,” he said.

Once the air-handling equip-

ment has been properly sized and selected, care must be taken to ensure that the supply air ducts, the chilled water lines (supply and return), and the refrigerant lines are well insulated, he said. With the cooler air inside the ducts or water inside the chilled-water piping, Nunnally warned that condensation can easily form on the outside of the ducts and/or pipes.

“The dew point temperature of the air surrounding the cooler ducts and pipes could easily be higher than the surface temperature of the ducts and pipes,” he said. “Condensation will occur when this happens.”

If the ducts and piping happen to be in the ceiling space, the condensate can drip onto a sur-

face that is loaded with mold — ceiling tiles, dry wall boards, insulation, plywood, etc. — “and all of the necessary elements are there for mold growth,” he said.

HUMIDITY CONTROL MATTERS

In his estimation, once the HVAC system has been selected and properly sized, serious consideration must then be given to

the controllability of the systems. It is his belief that most HVAC systems are installed with the primary function of either cooling or heating, with the humidity control simply as a secondary function of the system.

“This is evidenced by the fact that most HVAC systems are installed only with a thermostat installed to operate the system.”

said Nunnally. “Including humidity control devices in the controls package for the HVAC system is almost nonexistent. How can you control the humidity if it is not

even being measured?”

Also, far too often, the supply and return air ducts aren't sealed or insulated properly during construction, he said. On the return

side of the equipment, leaky ducts will draw in far more moisture than the cooling coils were designed to remove. The result, he said, is a higher than designed and desired humidity level in the space.

“In an effort to save installation dollars, the return duct is often deleted from the plans and the interstitial space between the suspended ceiling and the roof assembly, or the floor assembly above, is used as a return plenum,” he said.

“Little thought is given to the fact that this interstitial space is now under a substantial negative pressure and this could cause moisture-laden ambient air to be drawn into the space from an outside wall through cracks and holes if this space is not sealed adequately. This infiltration air is completely unconditioned at this point.”

Nunnally is quick to point out there is more to consider, but all should start with the basics first.

“The HVAC system, the heart and lungs of the facility, must be selected and sized properly for its very important task,” he summarized. “And that task is to control the environment to promote the healthiest conditions possible for the patients and the health care providers.” ■

Recognition. Respect. Rewards. Finally, a career that has it all.

ARS/Rescue Rooter, one of the nation's leading HVAC and plumbing service providers, is seeking well-qualified individuals to fill General Manager positions throughout the country.

Our General Managers enjoy:

- ★ An entrepreneurial environment fostering personal satisfaction from a challenging and rewarding career
- ★ A high level of respect and recognition within our organization
- ★ Industry-leading salaries with performance-based bonus opportunities
- ★ Personal and professional growth through career advancement opportunities
- ★ Comprehensive benefits, including medical, dental, vision, PTO, 401K
- ★ The support, resources and stability of an established national company
- ★ Responsibility and accountability for sales and operations with revenues in the millions

For more information, visit ARS.com/gmcareers or email your resume in confidence to gmcareers@ARS.com.

All candidates are required to undergo pre-employment drug screening and background checks.
